An EMC/EMI system-design and testing methodology for FPD-Link III SerDes. Introduction. Automotive electromagnetic compatibility (EMC) tests are broadly classified into two areas: 1) Radiated emissions tests that analyze the electromagnetic interference (EMI) or noise generated by the system as an " aggressor " , and 2) System electrostatic-discharge (ESD) and bulk-current injection (BCI) tests that measure the " immunity " of the system as a " victim " to ambient emissions.

LearnEMC - Electronic Systems Design for EMC Compliance

Electromagnetic compatibility(EMC) is the ability of electrical equipment and systems to function acceptably in their electromagnetic environment, by limiting the unintentional generation, propagation and reception of electromagnetic energy which may cause unwanted effects such as electromagnetic interference(EMI) or even physical damage in operational equipment.

ESD compliance according to the EMC directive is based on IEC 1000-4-2. This standard specifies a Human Body model that tries to emulate the ESD a product will experience as a result of normal use. The component values are therefore slightly tougher here than in MIL-STD-883: RCis 100M , RDis 330 , and CCis 150pF.

Electromagnetic Compatibility(EMC) and Electrostatic Discharge(ESD) immunity must be considered in the early design phase of a system. This is also true for the application of liquid crystal displays and the accompanying drivers. If ignored, problems encountered later during testing or in the field will become very difficult and expensive to fix, whereas in the early development stage, measures to improve EMand ESD immunity can be implemented at low cost or often even for free.

The first part of system-level design for ESD is to prevent entry of the ESD discharge inside the enclosure. It ' s best, but not always possible, to prevent an ESD event from occurring in the first place. This should be an easy task to accomplish if your product is contained in a non-metallic/plastic enclosure.
